

AirpruneRack

AirpruneRack is a wire rack designed to create growing space beneath the tray, by lifting up the tray. This results in natural air pruning, which prevents the roots from growing under the tray.

What are the most important reasons to start using use AirpruneRack?

- AirpruneRack creates a layer of air that prevents a capillary space with (heated) moisture.
- The air circulation beneath the trays prevent root growth underneath, which results in a compact root ball in the cups of the trays.
- Since the energy remains in de tray, the product will grow faster and will be of higher quality.
- Because the roots are no longer pulled from the soil, they will not be damaged nor will they become susceptible to pathogens.
- The trays can be delivered with all roots intact, which will ensure continued growth and optimal quality.
- It is no longer necessary to remove roots from the bottom of the trays, this will save money on labour costs.

In practice, it appears that the best height at the bottom of the tray is between 70 and 100 mm. This can be adjusted to the situation. AirpruneRack can be used on the ground and on growing tables. The length and width of AirpruneRack, along with the distribution of the wires, can be adjusted to your particular tray.
